Modulated Electroluminescence for Minority-Carrier Relaxation in HJ-Si and CIGS Cells (PVCore-2)

A joint India-U.S. research consortium funded under the *Joint Clean Energy Research & Development Center (JCERDC)*

Scientific Achievement:

Relaxation time of minority carriers in solar cells is obtained from the frequency dependence of inphase (A_{in}) and quadrature (A_{quad}) components of modulated electroluminescence (MEL) using standard electrical equipment.

Significance and Impact:

In MEL, the relaxation time is obtained from the frequency at which the quadrature component peaks, independent of a knowledge of material parameters such as mobility. Hence, it can be used for any finished cell that has detectable light emission.

Research Details:

SERI IUS

- For silicon solar cells, the relaxation is dominated by recombination and the relaxation time is the minority-carrier lifetime.
- In contrast, for the CIGS solar cells, the relaxation time is dominated by trapping and emission from shallow minoritycarrier traps.
